Nanoparticle vs. Magnetic Properties

Magnetic Anisotropy

$$H_{ex} = -2 \sum_{i < j} J_{ij} \vec{S}_i \cdot \vec{S}_j - K \sum_i (S_{zi})^2$$

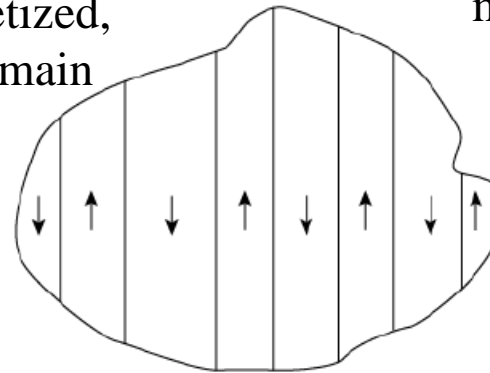

Bulk Co in its demagnetized, multi-domain state

Minimization of magnetostatic energy

$$U_B = \frac{1}{2\mu_0} \int_{allspace} B^2 d\tau$$

leads to domain wall formation

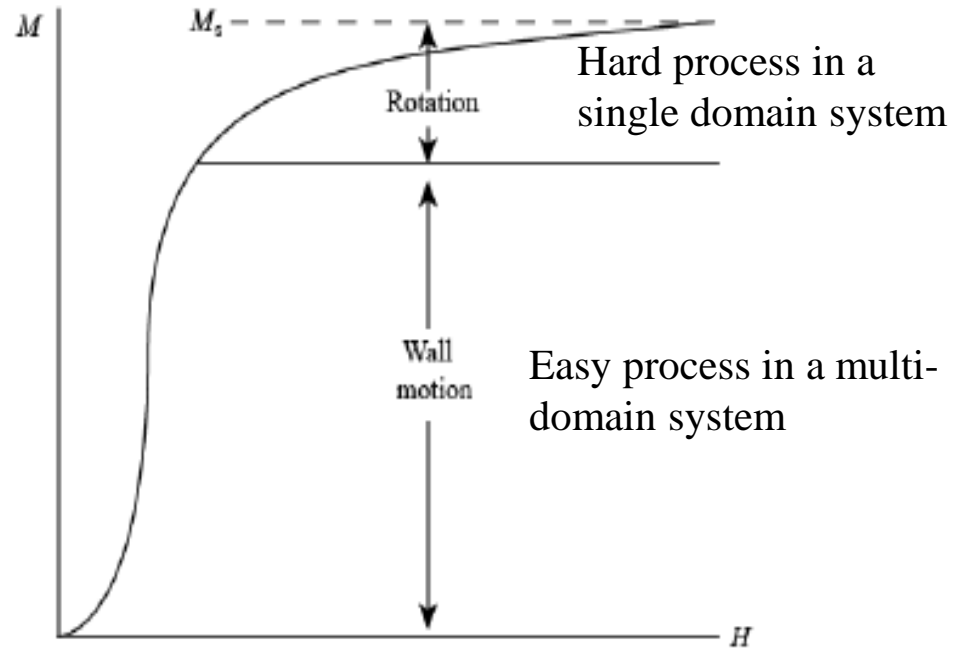

Moment rotation at a Bloch Wall

Uniaxial Magnetic Anisotropy

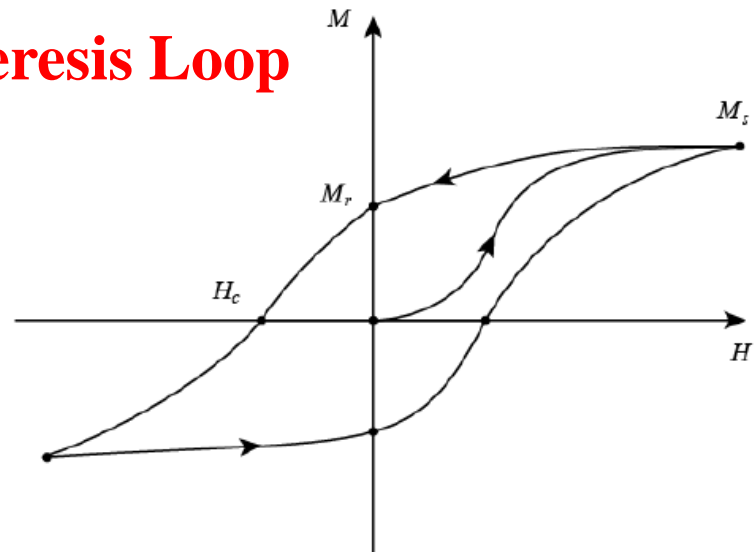

Anisotropy Field $H_{an} = \frac{2K}{\mu_0 M_s}$

Exchange energy per unit area of Bloch wall $\sigma_{BW} = \pi \sqrt{AK}$ where $A = \frac{2J_{ex} S^2}{a}$

for a simple cubic lattice with lattice constant a .

Hysteresis Loop

The hysteresis loop defines the technological properties of the magnetic material

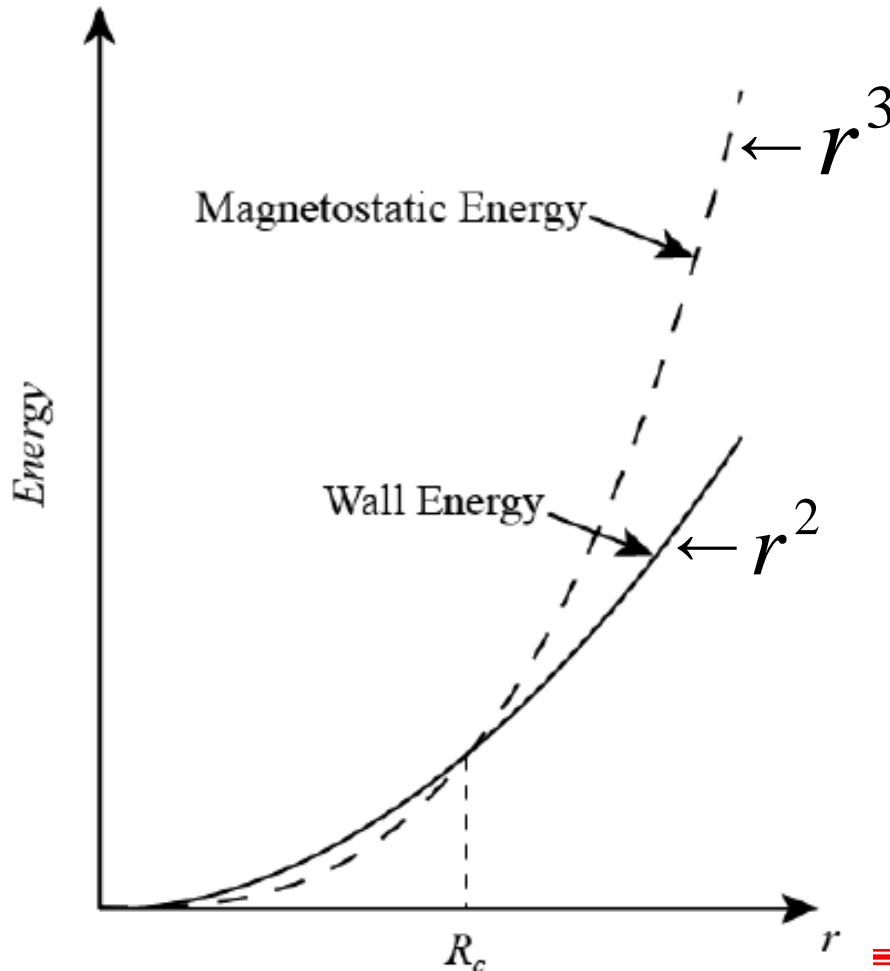

M_s = Saturation Magnetization

M_r = Remnant Magnetization

H_c = Coercivity

Critical Size for SMD Particles

Magnetostatic vs. wall energy as a function of particle size for a spherical particle of radius r

$$R_C = R_{SMD} = \frac{6\sqrt{AK}}{\mu_0 M_s^2}$$

Below R_c the particle is a Single Magnetic Domain, and thus permanently magnetized. The demagnetized state cannot be formed.

$$R_c \sim 100 \text{ nm}$$

Coercivity as a function of particle size

Nanomagnetism: Coercivities and Spin Reversal Mechanisms

Single-magnetic domain particle
Coherent spin rotation

Multi-magnetic domain structure
Magnetic wall movement

Nanoparticle
 $K \sim 10^5 \text{ J/m}^3$

Bulk
 $K \sim 10^3 \text{ J/m}^3$

Origin of magnetic anisotropy enhancement in nanoparticles

Inverse particle diameter (nm⁻¹)

F. BØAKER, S. MØRUP, S. LIAERØIN, Phys. Rev. Lett. 72 (1994) 282

$$K_{eff} = K_c + \frac{6K_s'}{D}$$

$$K_{eff} = K_c + K_s + K_\sigma + K_{sh}$$

c = core

s = surface

σ = stress

sh = shape

Nanoparticle coercivity for coherent spin rotation (Stoner and Wohlfarth model)

Easy axis
(axis of revolution)

coherent
moment
rotation

Maximum coercivity for coherent spin rotation of a single magnetic domain particle with uniaxial total effective anisotropy

$$H_c = \frac{2K_u}{\mu_0 M_s}$$

E.C. Stoner, E.P. Wohlfarth, *Trans. Roy. Soc. Lond.*
A 240 (1948) 599

Spin Dynamics in Magnetic Nanoparticles

Temperature dependence of coercivity

$$H_c = \frac{2K_u}{\mu_0 M_s} \left[1 - \left(\frac{25kT}{K_u V} \right)^{1/2} \right] \quad (\text{thermally assisted spin reversals})$$

Superparamagnetic relaxation time

$$\tau = \tau_0 \exp\left(\frac{K_u V}{kT}\right)$$

Due to fast moment reversals at elevated temperatures the internal magnetic order of the particle escapes detection. You must either lower the temperature or use ultrafast measuring techniques that can record the moment before it flips.

Superparamagnetism of Small Magnetic Particles

Energy barrier
 $\Delta E = K_u V$

where K_u is the
effective uniaxial
magnetic anisotropy
Energy density and V is
the particle volume

Relaxation Time

$$t_{RELAX} = t_0 \exp(K_u V / kT)$$

Magnetocrystalline Anisotropy

Shape Anisotropy

Surface effects

Observe net magnetic moment
when

$$t_{MEAS} < t_{RELAX}$$

Micro-magnetics and Spin Dynamics

-Mössbauer spectroscopic measurements

Probe local magnetic moments and internal magnetic fields, with a response time of

$$\tau_m = \tau_{\text{Möss}} = 10 \text{ ns}$$

-DC Magnetization measurements

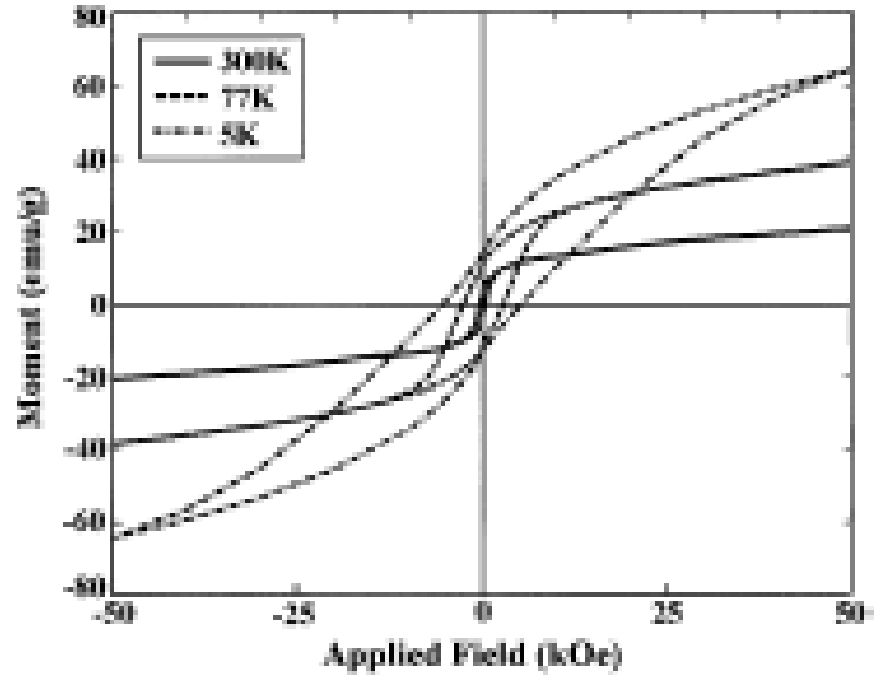

Probe global magnetic properties in an applied field, with a response time of

$$\tau_m = \tau_{\text{SQUID}} = 10 \text{ s}$$

Hysteresis Loops for CoFe_2O_4 Block Copolymers

Hysteresis due to particle moment rotation away from the particle's easy axis to the direction of the applied magnetic field.

The temperature at which the coercivity vanishes defines the blocking temperature T_B for SQUID magnetometry.

Ahmed, Ogal, Papaefthymiou, Ramesh and Kofinas, *Appl. Phys. Letts* 80 (2002) 1616

Modeling Dynamical Spin Fluctuations in Isolated Nanostructures

Determination of Blocking Temperature

Experimentally the temperature at which the Mössbauer spectra pass from magnetic, six-line spectra to paramagnetic or quadrupolar, two-line spectra defines T_B for Mössbauer

Theoretically T_B is defined by:

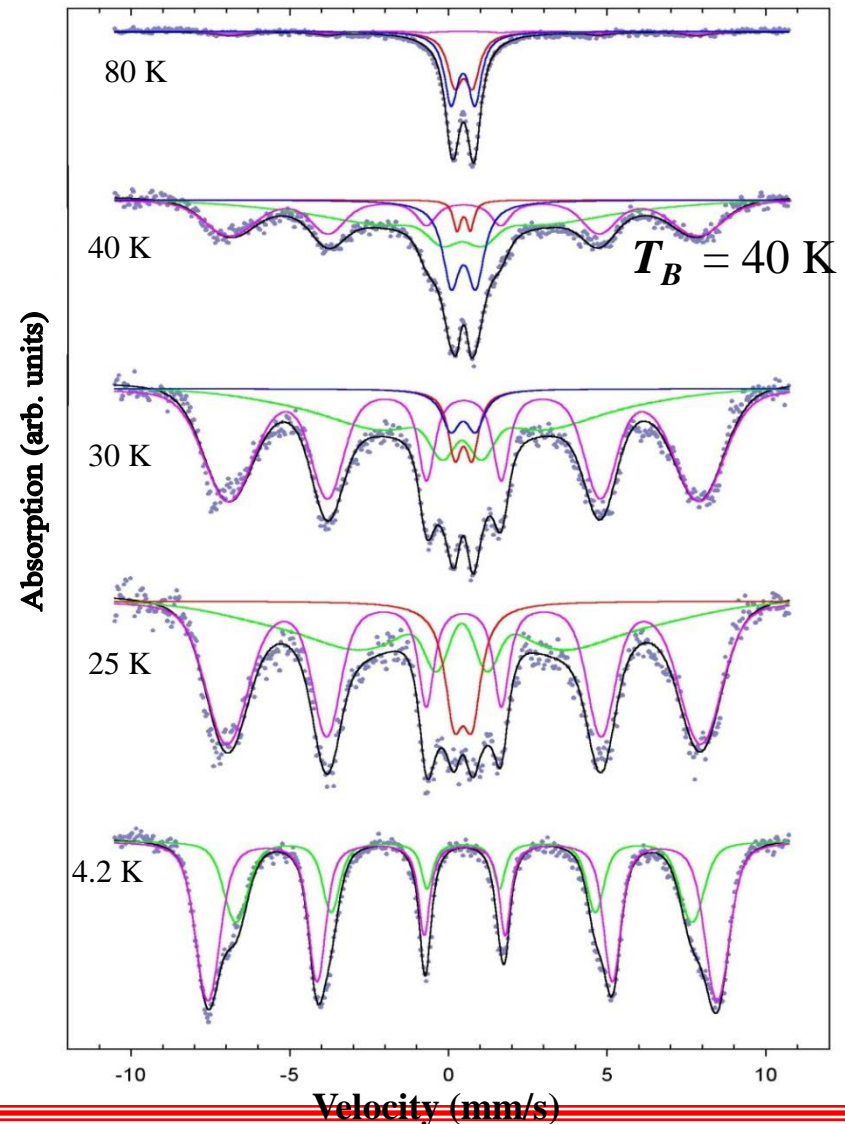

$$\tau_m = \tau_0 \exp\left(\frac{K_u V}{kT_B}\right) \rightarrow T_B = \frac{K_u V}{k \ln(\tau_m / \tau_0)}$$

Spectrum Key

Magenta: spectral signature of magnetic particle core (internal iron sites)

Green: spectral signature of surface layers (surface iron sites)

Mössbauer spectra of lyophilized, *in vitro* reconstituted HoSF ferritin.

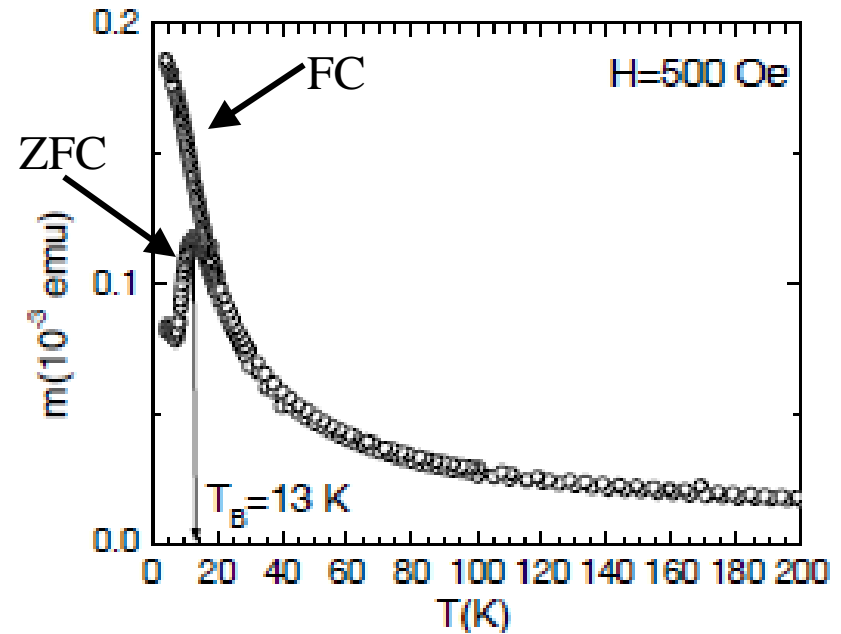

25-nm thick protein shell

Note: Saturation magnetization is ~ 0.05 emu/g, weakly magnetic.

Zero-field cooled and field-cooled magnetization of lyophilized HoSF ferritin

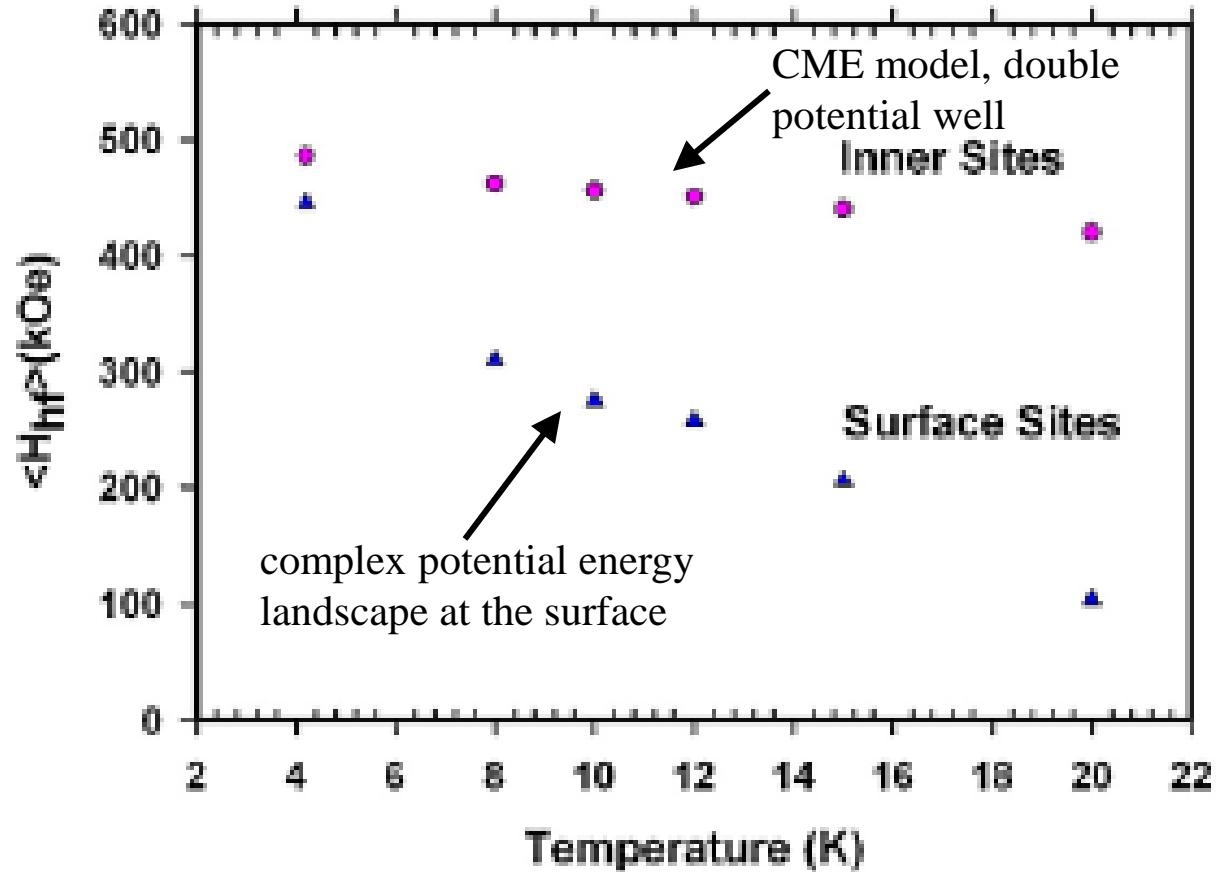

Typical ZFC/FC behavior of an ensemble of magnetically isolated superparamagnetic particles

Determination of K_u for an ensemble of superparamagnetic nanoparticles

$$\tau = \tau_0 \exp\left(\frac{K_u \langle V \rangle}{kT}\right) \longrightarrow \tau_m = \tau_0 \exp\left(\frac{K_u \langle V \rangle}{kT_B}\right)$$

1. Determine average particle volume $\langle V \rangle$ by TEM
2. Determine T_B with two different techniques, whose measuring response times lie in different time windows
3. Use the Arrhenius equation above to determine τ_0 and K_u

Surface Effects: Temperature Dependence of Mössbauer Magnetic Hyperfine Fields

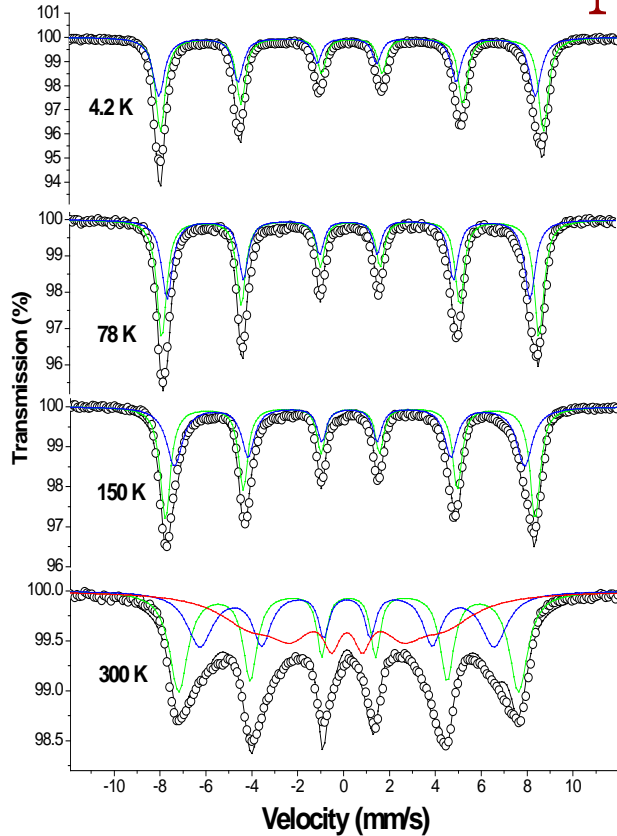

$$H_{hf}(T) = H_{hf}^0 \left(1 - \frac{kT}{2K_{eff}V} \right)$$

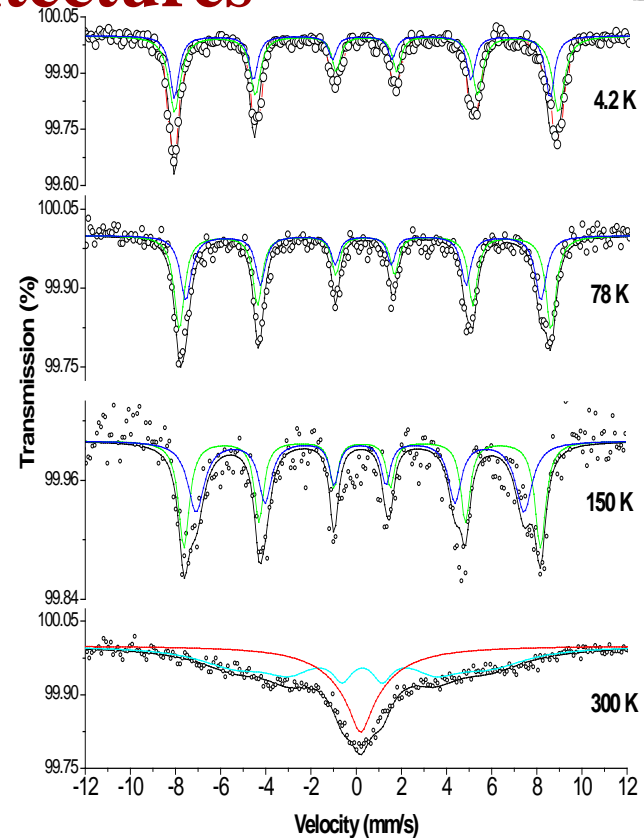

S. Mørup and H. Topsøe, *Appl. Phys.* 11 (1976) 63

Mössbauer Spectra of $\gamma\text{-Fe}_2\text{O}_3$ /Solid Silica Nanoarchitectures

Effect of silica shell on the RT Mössbauer Spectra

Behavior typical of strongly interacting particles

Bare $\gamma\text{-Fe}_2\text{O}_3$ nanoparticles

$\gamma\text{-Fe}_2\text{O}_3$ nanoparticles with 4 nm silica shell

$\gamma\text{-Fe}_2\text{O}_3$ nanoparticles with 25 nm silica shell

Magnetization of $\gamma\text{-Fe}_2\text{O}_3$ /Solid Silica/Mesoporous Silica Nanoarchitectures

A-bare *

B-4 nm (S)

C-25 nm (S)

D-25 nm (S) + 10 nm (MS)

E-25 nm (S) + 21 nm (MS)

Typical behavior of strongly interacting magnetic nanoparticles, spin-glass-like systems.

* Bare particles are covered with a very thin layer (~1 nm) of oleic acid. Saturation magnetization of the order of ~ 8 emu/g, strongly magnetic

Conclusion

Ferrihydrite is an *antiferro*-magnet.
Magnetization of ferritin is due to uncompensated spins at the surface → Weak magnetism. Protein coat of only 2.5 nm thickness sufficient to magnetically isolate the ferritin iron cores

Maghemite is a *ferri*-magnet due to uncompensated spin sublattices in its spinel structure. In small particles uncompensated spins at the surface also contribute → Strong magnetism. Silica coat of 23 nm thickness insufficient to isolate the $\gamma\text{-Fe}_2\text{O}_3$ cores

$$\text{Dipole-dipole interaction} \sim \frac{\vec{\mu}_1 \cdot \vec{\mu}_2}{r^3}$$

Summary

Seagate HAMR Demo

Dr. Steve Hwang, Vice President Media R&D,
Seagate Technology, RMO Fremont

1007 Gbps (1975 kbp/track x 510 ktpi)

Demo Criteria

- Adjacent tracks written both sides at track pitch with the same laser power and pattern as data track
- On-track bit error rate = $10^{-2.0}$ with no correction/iterations

Limiting factors

- Head Media Spacing
 - much larger than state-of-the-art PMR
 - media roughness, coating thickness, head thermo-mechanical, and clearance management
- Media Distributions
 - distributions much larger than PMR
 - large effective gradient helps
- Electronic Noise
 - Lower Mrt and high HMS

Key Elements of HAMR Media Design

Good Microstructure

Well Defined Thermal Profile

Good Texture and Ordering

- compared to CoCrPt alloys used in PMR
FePt L1₀ materials used for HAMR media offer
- higher anisotropy
⇒ larger stability
 - lower T_C
 - larger dH_K/dT
 - tunable by doping, e.g., with Ni or Cu

Magnetics & Distributions

HAMR vs PMR Media Loops

Media Design Constraints – “Trilemma”

Media SNR
 $SNR \sim \log_{10}(N)$
Small Grains (V)

We are now down to 6-10 grains per bit !

Thermal Stability

$$E_B \cong K_u V \left[1 - \frac{|H_d|}{H_0} \right]^2$$

$$K_u V = 40-80 k_B T$$

Writability

$$H_0 = \alpha \frac{2K_u}{M_s} - N_{eff} M_s$$

$H_0 < \text{Head Field}$

D. Weller and A. Moser, “Thermal Stability Limits in Magnetic Recording” IEEE Trans. Mag. 35 4423 (1999) **IBM**

Smallest thermally stable grain size - details

$$\tau = f_0^{-1} e^{E_B/k_B T_S}$$

$$E_B = K_V \left(1 - \frac{4\pi M_S}{H_K} \right)^2$$

f_0 : attempt frequency $\cong \alpha\gamma H_K \cong 10^9 - 10^{12}$ Hz

$E_B/k_B T_S = \ln(f_0 \tau) = r_K \sim 50$ for $\tau = 10$ years

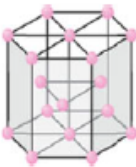

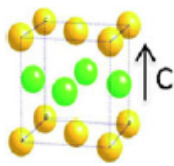

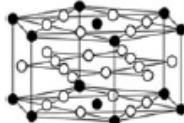

$$D_p = \left(k \frac{2 \cdot r_K \cdot k_B T_S}{H_K M_S \left(1 - \frac{4\pi M_S}{H_K} \right)^2} \right)^n$$

δ		$n=1/2, k=4/\pi\delta$ for cylinders
		$n=1/3, k=1$ for cubes
		$n=1/3, k=6/\pi$ for spheres
$\delta/D=4$		$n=1/3, k=1/4$ for prisms

“Early” FePt HAMR media microstructure – spherical grains

Granular FePtAg-C media grown at $\sim 550^\circ\text{C}$ 2011

Graphitic Sheets

- ❖ Used a new Lean 200 sputter tool w/ 20 chambers
- ❖ Low thickness $\delta \sim 7 \text{ nm}$ and relatively high roughness
- ❖ Average grain size $\langle D \rangle \sim 7.2 \text{ nm}$, grain pitch $\langle P \rangle \sim 9 \text{ nm}$
- ❖ grain aspect ratio $\delta/D \sim 1$
- ❖ many small grains $D < 3 \text{ nm}$ (thermally unstable)

Importance of Columnar Grains

Spheres

VS.

Columns

Graphitic Sheets

Advantages of columnar grain growth:

- Decouple grain diameter from grain thickness.
- Thicker media will increase readback signal.
- Smoother surfaces and better flyability.
- Get laterally smaller, thermally-stable grains.
- Narrow distribution in optical absorption and consistent vertical heat flow from grain to grain.
- Enable functional layered structures.

Effect of grain size and aspect ratio on T_c - Modeling

Modeling

Finite size scaling theory $T_c(D) = T_c(\infty) \left(1 - x_0 D^{-1/\nu}\right)$ $\nu \sim 0.7 \pm 0.09$

- T_c smaller than 750 K due to exchange truncation/abandonment in single particle modeling
- Cylindrical grains with an aspect ratio of ~ 2 reduce x_0 by $\sim 20\%$, i.e. “minimize” the grain size induced reduction of T_c
- $\nu = 0.7 \pm 0.09$ is compatible with 3D Ising/Heisenberg models
- T_c determined from peak susceptibility $\chi(T)$ using Monte Carlo method

A. Lyberatos, D. Weller, G. Parker, “Finite size effects in $L1_0$ -FePt nanoparticles” J. Appl. Phys. 114, 233904 (2013)

σ_{T_C} vs grain diameter D_x

- Variations in T_c arise from the dispersion in grain size and chemical order.
- Recording performance is highly sensitive to T_c and H_K distributions.
- **Reducing D increases σ_{T_C}/T_C from $\sim 1\%$ ($D=8\text{nm}$) to $\sim 2.5\%$ ($D=4\text{nm}$).**

Starting to count individual atoms ...

atom numbers	size (nm)
201	1.77
459	2.31
1289	3.27
2075	3.85
4033	4.77
5635	5.35
9201	6.31
11907	6.87

At ~3 nm diameter particles have 25-30% atoms on surface! Properties change as a result of that!

2 nm

Oleg Mryasov, 2003 (Seagate)

Particle Size Effects: 3d(Fe,Co)-5d/4d(Pt/Pd) High Anisotropy Alloys

Curie Temperature Reduction

Anisotropy Energy Reduction

Surface to volume fraction increases to 20-40% for 3 nm FePt particles (1000 atoms)

$$d_{ij}^{(2)} = \frac{k_{Pt}^{(0)}}{[J_{\mu}^0]^2} \sum_{\mu} J_{i\mu}^{Fe-Pt} J_{j\mu}^{Fe-Pt}$$

Finite size effects due to interactions mediated by induced Pt magnetic moment

“Structure and Magnetic Properties of $L1_0$ -Ordered Fe-Pt Alloys and Nanoparticles”

Table 5.2 The room temperature magnetic behaviour (para - paramagnetic; ferro - ferromagnetic; af - antiferromagnetic) and magnetic properties of the main phases in the Fe–Pt system: the Curie temperature T_c , the anisotropy constant K_1 , the anisotropy field $H_A = 2K_1/\mu_0M_s$, the saturation magnetisation M_s , the upper limit of energy density $(BH)_{max} = \mu_0M_s^2 / 4$, the domain wall-width δ_w , the exchange length l_{ex} and the critical single-domain particle size D_c .

Compound	Structure (space group)	Magnetic behaviour	T_c (K)	K_1 (MJ/m ³)	μ_0H_A (T)	μ_0M_s (T)	$\mu_0M_s^2 / 4$ (kJ/m ³)	δ_w (nm)	l_{ex} (nm)	D_c (nm)	References
α -Fe	$A2 (Im\bar{3}m)$	ferro	1043	0.046		2.16	928	30	1.5	7	Kneller and Hawig (1991), Skomski and Coey (1999)
